BENEFITS
As compared to TIG or MIG welding, the NASA torch offers:

- Enhanced accuracy: Variable lenses allow the user to adjust power in real time, depending on circumstantial welding needs.
- Increased portability and maneuverability: Handheld form allows the user to braze in small or hard-to-reach places.
- Improved user safety: Added sensors and emergency switches boost user safety.
- Decreased heat affected zone: The laser applies heat to a very localized working area to prevent damage to the welding surface.

APPLICATIONS
Opportunities include various welding applications where real-time laser variation may be needed due to spatial or accuracy constraints where traditional welding methods are cumbersome:

- Aerospace engine repair
- Medical hardware manufacturing
- Plastic mold and die restoration
- Jewelry manufacturing and repair
- Eyeglass frame welding
THE TECHNOLOGY

Features of the handheld torch’s design include manual controls to modify the laser diameter and power output in real time. These features allow the user to adjust the laser depending on circumstantial needs, resulting in a torch that is well suited for in-field repairs of metals where space and time are constrained. The primary applications are likely to be in-field welding and brazing of damaged specialized equipment where traditional welding systems cannot easily access the welding area.

The laser technology is a variable power, continuous wave, handheld fiber laser torch for brazing metals with an increased precision and maneuverability. The laser hardware and supply measures 24 inches in length, 15 inches wide, and 30 inches high, with a torch diameter of about 0.8 inches. This size is nearly half that of traditional welding systems, which increases the portability of the machine as well as the welder’s maneuverability.

The current handheld torch replaces earlier versions of handheld torches that cost over $700K to produce, with a large footprint over 60”. After numerous design improvements and the inclusion of a commercial off-the-shelf fiber laser, the third generation NASA torch has a much smaller footprint, with the handheld component being about 2.5 times larger than standard ink pens. The NASA handheld torch and system integration is estimated to cost between $60K and $70K.

NASA has used the handheld laser on Haynes 230 super alloy to improve localized repair procedures. Preliminary tests of the NASA handheld laser produced a consistent data set of yield strength (YS), ultimate tensile strength (UTS), and percent elongation (%EL) that are comparable to the results of current GTAW techniques.

Two sets of plates were welded, and six tensile specimens were evaluated and tested; comparable results to GTAW techniques are demonstrated. Weld specimen Plate 01 demonstrates full penetration of Haynes 230 super alloy using the handheld laser. Weld specimen Plate 02 demonstrates partial penetration of Haynes 230 super alloy using the handheld laser. GTAW data is from literature study, (Ernst 1994).

NASA’s Technology Transfer Program pursues the widest possible applications of agency technology to benefit US citizens. Through partnerships and licensing agreements with industry, the program ensures that NASA’s investments in pioneering research find secondary uses that benefit the economy, create jobs, and improve quality of life.
